[Inside Wall Street: Why Hocus-Pocus Accounting Will Perpetuate the Capital Markets Credit Crisis](#)

By Shah Gilani
Contributing Editor

I once asked my friend – world-famous magician Lance Burton – if he could show me how he did a particular trick.

“Can you keep a secret?” he asked.

“Of course,” I replied.

“So can I,” he said.

The point is that the U.S. Federal Reserve, the U.S. Treasury Department and federal regulators are keeping secret the true precariousness of the capital markets credit crisis and the banking system’s close-to-the-precipice predicament. They need to give banks and investment banks room to maneuver their balance sheets by whatever “hocus-pocus accounting” methods they can utilize – without being outright fraudulent. It’s a matter of putting on a good show to give the banks time to repair their balance sheets and build up capital, however long that takes and with whatever magic can be mustered.

No End in Sight

Contrary to once-prevalent expectations – including the early prognostications from the Fed and Treasury – the capital markets credit crisis is not abating. And as long as sleight-of-hand, hocus-pocus

accounting is prevalent, transparency will be thin, liabilities will be buried, losses will surprise investors, and capital will be both inadequate and expensive.

Accounting is not supposed to be that complicated. There shouldn't be any magic, trickery, or sleight-of-hand. The ugly truth is that, until housing prices bottom out, no amount of hocus-pocus accounting will fix the problems that fed into the capital markets credit crisis. Hiding problems only delays the day of reckoning. In short, given our present set of circumstances, ugly is not just skin deep. And there is no rabbit to be pulled from the hat.

Attendant to the magic of hocus-pocus accounting are numerous sideshows that further mask mortgage-related liabilities. One easy-to-spot trick is the lengthening of the measure under which banks consider loans to be troubled, or categorized as non-performing assets. The sleight-of-hand occurs when a bank redefines troubled loans to be non-performing when the borrower is three payments behind versus two payments, or when it moves the target for "anticipation of borrower default" out to 180 days from 120 days.

Pick a target: If you're afraid they'll hit it, just move the target.

The Basel Boondoggle

It's not enough that subjective [Financial Accounting Standards Board](#) (FASB) asset-classification standards and subjective fair value accounting methodologies provide the dagger in the heart of transparency; there are additional knives and swords available and widely employed with which to slice and dice asset values in order to cloak capital inadequacy and actual losses.

Besides deferring losses, banks and investment banks manipulate critical measures of capital adequacy in order to remain, in the eyes of regulators and the public, adequately capitalized and solvent. Tier 1 capital, the principal measure of adequate equity capital, consists of shareholder equity, irredeemable preferred stock and retained earnings. The more Tier 1 capital a bank has, supposedly, the safer it is.

The calculation of Tier 1 was established by the [Basel Accord of 1988](#) under the auspices of the Bank of International Settlements (BIS). The 1988 Accord, known as Basel I, was updated in 2004. The modified accord is known as Basel II.

A bank's Tier 1 *capital ratio* is the ratio of the bank's equity capital to its risk-weighted assets. The ratio is important because it serves as a window into leverage and risk. The problem with the capital-ratio measure is the potential for manipulation in the calculation of "risk-weighting."

How banks weight the riskiness of assets is too often a result of bank's managing their capital. In

other words, it's a bottom-up process: Determine what capital is required and then manage the books to meet that measure.

The classification of assets as *available-for-sale* is a perfect example of burying liabilities to meet capital requirements. "Available-for-sale" gives management the option to account for assets as if they might be saleable now and priced concurrently or whether, maybe, they will be held to maturity and not have to be priced according to their present fair value.

What's even better for banks when they use this magic trick is that losses, no matter how large, reside in the netherland of *accumulated other comprehensive income*, the accounting line on the balance sheet that available-for-sale assets flow down to. And those losses are not included in Tier 1 calculations!

There are other problems with implementation of the Basel Accords. Commercial banks, overseen by the Fed, follow Basel I guidelines for Tier 1 ratios. Investment banks, overseen by the [U.S. Securities and Exchange Commission](#), calculate Tier 1 ratios based on Basel II guidelines.

Investment banks are deemed to have it easier because Basel II allows greater management flexibility in weighting risk and allows the incorporation of ratings and internal modeling into that process. It's enough to know that manipulation is manifest. That much is clear, especially with all the pain that trumped-up – and downright corrupt – ratings have already caused in the massive subsequent downgrading of credit instruments. [Federal Deposit Insurance Corp.](#) Chairman [Sheila C. Bair](#) has actually stated that Basel II [essentially lets "banks set their own capital requirements."](#)

One fine point of the Basel I Accord differentiated between banks holding mortgages on their books and those holding mortgage-backed securities, in terms of the capital to be held against these different assets. Holding mortgages required more capital since, technically speaking, mortgages are technically less liquid than tradable security instruments. The result was a wholesale exit from holding individual mortgages and a rush into [mortgage-backed securities](#).

Now You See it ...

Having to hold capital against assets as a cushion against future losses ties up otherwise productive capital. Anywhere those capital requirements can be reduced frees up that released capital to be employed elsewhere in leveraging the balance sheet. The ultimate device to free up capital was not merely accounting sleight-of-hand to pare back capital-reserve requirements, it became the ultimate magic trick – *the disappearing act*.

In order for banks and investment banks to make their capital-reserve-holding requirements disappear, they would have to make the assets against which capital needed to be held disappear. And, with a wave of the wand and the magic words hocus-pocus, they did. Welcome to the world of "now you see it, now you don't" – better known as "[structured investment vehicles](#)" (SIVs) and conduits.

SIVs are generally offshore entities set up to warehouse assets that would otherwise be subject to bank capital reserve requirements. A conduit is the generic name for an SIV; it is a conduit because it is a reciprocating channel for buying back [asset-backed securities](#) (ABS) previously sold into the capital markets by the banks. Banks fund SIVs with short-term commercial paper issuance, massively

leverage their borrowed capital, and buy huge amounts of ABS instruments.

They don't need to waste capital on reserve requirements because SIVs are not banks, and are therefore not subject to capital-reserve requirements. They are virtual banks without the regulatory hassles.

Doesn't anybody out there remember what happened when the now-defunct [Enron Corp.](#) employed these vehicles and manipulated their earnings?

The problem with this ultimate accounting fraud is that banks are potentially going to have to take their SIV assets back onto their books, haircut capital for reserves and eat the losses that have been hidden by accounting gimmickry at the SIV level. It's massive. But, because it is so massive and dangerous for banks' liquidity and a potentially devastating blow to their capital adequacy, regulators, including the Fed and Treasury, have yielded to delaying until 2010 the requirement that banks take these off-balance sheet assets, or more correctly, liabilities, back on to their books. Citi alone is estimated to have some \$600 billion to \$700 billion of SIV assets.

Once banks repatriate their SIV assets back onto their balance sheets, they will employ the full magic of accounting sleight-of-hand to bury liabilities in their efforts to struggle to maintain capital adequacy. Understanding some of the hocus-pocus accounting ticks – which I shall unmask in my follow-up piece tomorrow (Thursday) – will help investors look behind the curtain as they attempt to measure the worth of banks and investment banks and gauge the true duration of the capital markets credit crisis.

[Editor's Note: Contributing Editor R. Shah Gilani has toiled in the trading pits in Chicago, run trading desks in New York, operated as a broker/dealer and managed everything from hedge funds to currency accounts. In his new column, "[Inside Wall Street](#)," Gilani promises to take readers on a journey through the "shadowy back alleys" of the U.S. capital markets - and to conduct us past the "velvet rope" that guards Wall Street's most-valuable secrets - in an ongoing search for the investment ideas with the biggest profit potential. In Part II of his commentary on "hocus-pocus accounting" tomorrow (Thursday), Gilani will "unmask" three of the actual accounting maneuvers that fed into the capital markets credit crisis.]

Mathematical Concept Used by Gov't Code Breakers Can Predict the Market's Movement...

The CIA uses it to crack codes. The government uses it for technological superiority. The B-2 bomber couldn't fly without it. And for those that know how, it can be used to "speak the language" of the market.

But cutting through the "noise" and seeing through to the underlying hidden order of the markets, this strategy can be used to predict the movement of any investment - to the penny - with 95% accuracy.

And now for the first time, this strategy is being offered to a few investors as a reliable, emotion free guide to avoiding losses and making big money in these turbulent markets. [See if you qualify, here.](#)

[...] This kind of stuff is out there. There's a lot of it. And only an act of God will bring these securities back from the depths where they now reside. With their collateralized premise and structured nature, CDOs are very difficult to value - especially since no one trusts anyone else's "internal valuation model." Since everyone is afraid of these securities because no one really knows what they're actually worth, no one wants to buy them. However, when an

institution - such as a Merrill Lynch & Co. Inc. (MER) - gets desperate enough to sell a portfolio of these securities at 22 cents on the dollar, then everyone else who has to "mark-to-market" their assets now has to value similar securities of their own at 22 cents on the dollar. That causes massive write-downs at banks, investment banks, insurance companies, and other financial institutions. And these companies write down assets and watch their losses escalate, they are forced to raise additional capital to meet regulatory requirements. [...]

URGENT NEWS... That Could Save You \$85,000 this Year

Analyst Peter Schiff just discovered a mysterious but powerful force behind slumping stocks... crashing real estate... soaring food and gas prices... and the falling dollar.

Over the next 12 months, it will slash the net worth of every average American by \$85,000. The good news: Not only can you protect your money... **You can grow five times wealthier along the way.**

**For free details,
please [CLICK HERE](#) now...**

The Week Ahead	
December 23	GDP (3rd Quarter)
	Existing Home Sales (11/08)
	New Home Sales (11/08)
December 24	Initial Jobless Claims (12/20)
	Durable Goods Orders (11/08)
	Personal Income/Spending (11/08)
December 25	Christmas Day

The CIA Uses It to Crack Codes... Now It Predicts Volatile Markets

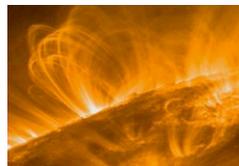

Government mathematicians use it for high-level code breaking. And without this one formula, the B-2 bomber couldn't fly an inch off the ground. Now it's being used to "speak the language" of the market – **with a 95% accuracy**. Part of the formula looks like this:

$$0109(X) + 1(g)667(Uk+I)$$

It's making a handful of savvy investors extremely wealthy by taking emotion – and losses – out of the game.
